Abstract. Previous work has shown a relation between L-valued extensions of FCA and the spectra of some matrices related to L-valued contexts. We investigate the spectra of reducible matrices over completed idempotent semifields in the framework of dioids, naturally-ordered semi-rings, that encompass several of those extensions. Considering special sets of eigenvectors also brings out complete lattices in the picture and we argue that such structure may be more important than standard eigenspace structure for matrices over completed idempotent semifields.

1 Motivation

The eigenvectors and eigenspaces over certain naturally ordered semirings called dioids seem to be intimately related to multi-valued extensions of Formal Concept Analysis [1]. For instance [2, 3] prove that formal concepts are optimal factors for decomposing a matrix with entries in complete residuated semirings. Notice the strong analogy to the SVD, with formal concepts taking the role of pairs of left and right eigenvectors.

Indeed, [4] prove that, at least on a particular kind of dioids, the idempotent semifields, formal concepts are related to the eigenvectors of the unit in the semi-ring. This result, however, cannot be unified with the former both for theoretical reasons, since idempotent semifields are incomplete (see below), as well as for practical reasons, since the carrier set of idempotent semifields is almost never included in \([0,1]\).

A possible way forward is to develop these theories under the common framework of the \(L\)-fuzzy sets, where \(L\) is any complete lattice [5]. Such an endeavour has already been called for [6], although it remains unfulfilled, hence this paper has a two-fold aim:

1. to clarify the spectral theory over completed idempotent semifields, and
1. to take steps towards a common framework for the interpretation of L-
Formal Concept Analysis as a spectral construction.

First steps have been taken in this direction with the development of a spectral
theory of irreducible matrices \([7]\) over complete idempotent semifields, whose
summary we include below, but the general case, here presented, shows a more
intimate relation to lattice theory.

### 1.1 Dioids and their spectral theory

A **semiring** is an algebra \( S = (S, \oplus, \otimes, e) \) whose additive structure, \( (S, \oplus, e) \),
is a commutative monoid and whose multiplicative structure, \( (S, \otimes, e) \), is a
monoid with multiplication distributing over addition from right and left and
with additive neutral element absorbing for \( \otimes \), i.e. \( \forall a \in S, e \otimes a = e \).

Let \( \mathcal{M}_n(S) \) be the semiring of square matrices over a semiring \( S \) with
the usual operations. Given \( A \in \mathcal{M}_n(S) \) the right (left) *eigenproblem* is the task of
finding the right eigenvectors \( v \in S^{n \times 1} \) and right eigenvalues \( \rho \in S \) (respectively
left eigenvectors \( u \in S^{1 \times n} \) and left eigenvalues \( \lambda \in S \)) satisfying:

\[
  u \otimes A = \lambda \otimes u \quad \quad \quad A \otimes v = v \otimes \rho
\]

The left and right eigenspaces and spectra are the sets of these solutions:

\[
  \Lambda(A) = \{ \lambda \in S \mid \mathcal{U}_\lambda(A) \neq \{ e^n \} \} \quad \quad \quad \mathcal{P}(A) = \{ \rho \in S \mid \mathcal{V}_\rho(A) \neq \{ e^n \} \}
\]

\[
  \mathcal{U}_\lambda(A) = \{ u \in S^{1 \times n} \mid u \otimes A = \lambda \otimes u \} \quad \quad \quad \mathcal{V}_\rho(A) = \{ v \in S^{n \times 1} \mid A \otimes v = v \otimes \rho \}
\]

\[
  \mathcal{U}(A) = \bigcup_{\lambda \in \Lambda(A)} \mathcal{U}_\lambda(A) \quad \quad \quad \mathcal{V}(A) = \bigcup_{\rho \in \mathcal{P}(A)} \mathcal{V}_\rho(A)
\]

Since \( \Lambda(A) = \mathcal{P}(A^T) \) and \( \mathcal{U}_\lambda(A) = \mathcal{V}_\lambda(A^T) \), from now on we will omit refer-
ences to left eigenvalues, eigenvectors and spectra, unless we want to emphasize
differences.

With so little structure it might seem hard to solve (1), but a very generic
solution based in the concept of transitive closure \( A^+ \) and transitive-reflexive
closure \( A^* \) of a matrix is given by the following theorem:

**Theorem 1 (Gondran and Minoux, [8, Theorem 1]).** Let \( A \in S^{n \times n} \). If
\( A^* \) exists, the following two conditions are equivalent:

1. \( A_i^+ \otimes \mu = A_i^+ \otimes \mu \) for some \( i \in \{1 \ldots n\} \), and \( \mu \in S \).
2. \( A_i^+ \otimes \mu \) (and \( A_i^+ \otimes \mu \)) is an eigenvector of \( A \) for \( \epsilon \), \( A_i^+ \otimes \mu \in \mathcal{V}_\epsilon(A) \).

In [7] this result was made more specific in two directions: on the one hand, by
focusing on particular types of completed idempotent semirings—semirings with
a natural order where infinite additions of elements exist so transitive closures
are guaranteed to exist and sets of generators can be found for the eigenspaces—
and, on the other hand, by considering more easily visualizable subsemimodules
than the whole eigenspace—a better choice for exploratory data analysis.

Specifically, every commutative semiring accepts a canonical preorder, \( a \leq b \)
if and only if there exists \( c \in D \) with \( a \oplus c = b \). A **dioid** is a semiring \( D \)
where this relation is actually an order. Dioids are zerosumfree and entire, that is they have no non-null additive or multiplicative factors of zero. Commutative complete dioids are already complete residuated lattices. Similarly, semimodules over complete commutative dioids are also complete lattices.

An idempotent semiring is a dioid whose addition is idempotent, and a selective semiring one where the arguments attaining the value of the additive operation can be identified.

Example 1. Examples of idempotent dioids are
1. The Boolean lattice $\mathbb{B} = \langle \{0, 1\}, \lor, \land, 0, 1 \rangle$
2. All fuzzy semirings, e.g. $\langle [0, 1], \max, \min, 0, 1 \rangle$
3. The min-plus algebra $\mathbb{R}_{\min,+} = \langle \mathbb{R} \cup \{\infty\}, \min, +, 0 \rangle$
4. The max-plus algebra $\mathbb{R}_{\max,+} = \langle \mathbb{R} \cup \{-\infty\}, \max, +, -\infty, 0 \rangle$

Of the semirings above, only the boolean lattice and the fuzzy semirings are complete dioids, since the rest lack the top element $\top$ as an adequate inverse for the bottom in the order.

The second important feature of spectra over complete dioids, as proven in [7], is that the set of eigenvalues on complete dioids is extended with respect to the incomplete case, and it makes sense to distinguish those which are associated to finite eigenvectors, the proper eigenvalues $P_p(A)$, and those associated with non-finite eigenvectors, the improper eigenvalues $P(A) \setminus P_p(A)$.

Moreover, as said above, the eigenspaces of matrices over complete dioids have the structure of a complete lattice. But since these lattices may be continuous and difficult to represent we introduce the more easily-represented eigenlattices $L_\rho(A)$ and $L_\lambda(A)$, complete finite sublattices of the eigenspaces to be used as scaffolding in visual representations.

1.2 Completed idempotent semifields and their spectral theory

A semiring is a semifield if there exists a multiplicative inverse for every element $a \in S$, notated as $a^{-1}$, and radicable if the equation $a^h = c$ can be solved for $a$. As exemplified above, idempotent semifields are incomplete in their natural order. Luckily, there are procedures for completing such structures [9] and we will not differentiate between complete or completed structures.

Example 2. The maxplus $\mathbb{R}_{\max,+}$ and minplus $\mathbb{R}_{\min,+}$ semifields can be completed as,
1. the completed Minplus semifield, $\mathbb{F}_{\min,+} = \langle \mathbb{R} \cup \{-\infty, \infty\}, \min, +, -, -\infty, 0 \rangle$
2. the completed Maxplus semifield, $\mathbb{F}_{\max,+} = \langle \mathbb{R} \cup \{-\infty, \infty\}, \max, +, -, -\infty, 0 \rangle$

In this notation we have $\forall c, -\infty + c = -\infty$ and $\infty + c = \infty$, which solves several issues in dealing with the separately completed dioids. These two completions are inverses $\mathbb{F}_{\min,+} = \mathbb{F}_{\max,+}^{-1}$, hence order-dual lattices. Indeed they are better jointly called the max-min-plus semiring $\mathbb{R}_{\max,+}^{\min,+}$. □
In fact, idempotent semifields $K = \langle K, +, \cdot, \cdot^{-1}, \bot, e, \Gamma \rangle$, appear as enriched structures, the advantage of working with them being that meets can be expressed by means of joins and inversion as $a \land b = (a^{-1} \oplus b^{-1})^{-1}$. On a practical note, residuation in complete commutative idempotent semifields can be expressed in terms of inverses, and this extends to eigenspaces.

Given $A \in \mathcal{M}_n(S)$, the network (weighted digraph) induced by $A$, $N_A = (V_A, E_A, w_A)$, consists of a set of vertices $V_A = n$, a set of arcs $E_A = \{(i, j) \mid A_{ij} \neq \epsilon_S\}$, and a weight $w_A : V_A \times V_A \rightarrow S$, $(i, j) \mapsto w_A(i, j) = a_{ij}$. This allows us to apply intuitively all notions from networks to matrices and vice versa, like the underlying graph $G_A = (V_A, E_A)$, the set of paths $\Pi_A(i, j)$ between nodes $i$ and $j$ or the set of cycles $C_A^+$. Matrix $A$ is irreducible if every node of $V_A$ is connected to every other node in $V_A$ through a path, otherwise it is reducible.

We will use the spectra of irreducible matrices as a basic block for that of reducible matrices: if $C_A^+$ is the set of cycles of $A$ then $\mu_{\oplus}(A) = \oplus\{\mu_{\oplus}(c) \mid c \in C_A^+\}$ is their aggregate cycle mean. For finite $\mu_{\oplus}(A)$, let $\tilde{A}^+ = (A \otimes \mu_{\oplus}(A)^{-1})^+$ be the normalized transitive closure of $A$, and define the set of (right) fundamental eigenvectors of irreducible $A$ for $\rho$ as $\text{FEV}_\rho(A) = \{\tilde{A}_i^+ \mid \tilde{A}_i^+ = e\}$, with left fundamental eigenvectors $\text{FEV}_\rho(A^\top) = \text{FEV}_\rho(A)^\top$. Then,

**Theorem 2** ((Right) spectral theory for irreducible matrices, [7]). Let $A \in \mathcal{M}_n(K)$ be an irreducible matrix over a complete commutative selective radicable semifield. Then:

1. $\Lambda(A) = \bigcap_{\mathcal{R}} \{\bot\} = P(A)$ .
2. $\Lambda^\rho(A) = \{\mu_{\oplus}(A)\} = P^\rho(A)$ .
3. If $\rho \in P(A) \setminus P^\rho(A)$, then $V_\rho(A) = \{\bot^n, \top^n\} = L_\rho(A)$ .
4. If $\rho = \mu_{\oplus}(A) < \top$, then $V_\rho(A) = \langle \text{FEV}_\rho(A) \rangle_{\overline{K}} \supset L_\rho(A) = \langle \text{FEV}_\rho(A) \rangle_2$ .

In this paper we try and find analogue results to Theorem 2 for the reducible case. First, we completely describe the spectra with Theorem 3 in Section 3.1. Then, we provide in Section 3.2 a bottom-up construction of the eigenspaces of certain reducible matrices from that of their irreducible blocks, using from Section 2.2 a recursive scheme to render matrices over idempotent semifields into specialised Upper Frobenius Normal Forms (UFNF). Finally, we discuss our findings in Section 4 and relate them to previous approaches.

## 2 Preliminaries

### 2.1 Some partial orders and lattices

In this paper we assume familiarity with basic order notions as described in [1, 10]. We only introduce notation when departing from there.

Recall that every set $V$ with $|V| = n$ elements and a total order $\leq \subseteq V \times V$ is isomorphic to a lattice called the chain of $n$ elements, $\langle V, \leq \rangle \cong n$. When the relation is the empty order relation $\varnothing \in V \times V$, it is called an anti-chain of $n$ elements, $\langle V, \varnothing \rangle \cong \overline{n}$. Lattice $1 \cong 1$ is the vacuously-ordered singleton. Lattice
2 is the boolean lattice isomorphic to chain 2. Lattice 3 is a lattice lying at the heart of completed semifields, the 3-bounded lattice-ordered group $\perp < e < \top$, isomorphic to chain 3.

If set of order ideals of a poset $P$ is $\mathcal{O}(P)$, then

**Proposition 1** (\cite[Chap. 1]{10}). Let $\langle P, \leq \rangle$ be a finite poset. Then $\langle \mathcal{O}(P), \subseteq \rangle$ is a lattice obtained by the embedding $\varphi : P \rightarrow \mathcal{O}(P)$, $\varphi(x) = \downarrow x$, with $\forall A_1, A_2 \in \mathcal{O}(P)$, $A_1 \lor A_2 = A_1 \cup A_2$ and $A_1 \land A_2 = A_1 \cap A_2$.

Note that $x \leq y$ in $P$ if and only if $\downarrow x \subseteq \downarrow y$ in $\mathcal{O}(P)$. Furthermore, $\mathcal{O}(P)$ can be obtained systematically from the ordered set in a number of cases:

**Proposition 2** (\cite[Chap. 1]{10}). Let $\langle P, \leq \rangle$ be a finite poset. Then

1. $\mathcal{O}(P \oplus 1) \cong \mathcal{O}(P) \oplus 1$ and $\mathcal{O}(1 \oplus P) \cong 1 \oplus \mathcal{O}(P)$.
2. $\mathcal{O}(P_1 \cup P_2) \cong \mathcal{O}(P_1) \times \mathcal{O}(P_2)$.
3. $\mathcal{O}(P^d) \cong \mathcal{F}(P) \cong \mathcal{O}(P)^d$.
4. $\mathcal{O}(n) \cong n \oplus 1 \cong 1 \oplus n$.
5. $\mathcal{O}(\pi) \cong 2^n$.

### 2.2 An inductive structure for reducible matrices

Recall that a digraph (or directed graph), is a pair $G = (V, E)$ with $V$ a set of vertices and $E \subseteq V \times V$ a set of arcs (directed edges), ordered pairs of vertices, such that for every $i, j \in V$ there is at most one arc $(i, j) \in E$. If $(i, j) \in E$ then we say that “$i$ is a predecessor of $j$” or “$j$ is a successor of $i$”, and $E \in \mathcal{M}_n(\mathbb{E})$ is the associated relation of $G$. If there is a walk from a vertex $i$ to a vertex $j$ in $G$ we say that “$i$ has access to $j$” or $j$ is reachable from $i$, $i \rightsquigarrow j$. Hence, reachability is the transitive closure of the associated relation, $\rightsquigarrow = E^+ [11]$. However, vertices $j \in V$ with no incoming or outgoing arcs cannot be part of any cycle, hence $j \nRightarrow j$ for such nodes, so it is not reflexive, in general. $(\rightsquigarrow \cap I_V)$ is the reflexive restriction of $\rightsquigarrow$, that is, the biggest reflexive relation included in it.

If there is a walk from a vertex $i$ to vertex $j$ in $G$ or viceversa we say that $i$ and $j$ are connected, $i \rightsquigarrow j \vee j \rightsquigarrow i$. Connectivity is the symmetric closure of the reachability relation: its transitive, reflexive restriction is an equivalence relation on $V_G$ whose classes are called the (dis)connected components of $G$. Note that each of the (outwards) disconnected components is actually (inwards) connected. Let $K \geq 1$ be the number of disconnected components of $G$. Then $V$ and $E$ are partitioned into the subsets of vertices $\{V_k\}_{k=1}^K$ and arcs $\{E_k\}_{k=1}^K$, of each disconnected component $\bigcup_k V_k = V$, $V_k \cap V_l = \emptyset, k \neq l$, $\bigcup_k E_k = E$, $E_k \cap E_l = \emptyset, k \neq l$ and we may write $G = \bigcup_{k=1}^K G_k$ is a disjoint union of graphs. $G$ is called connected itself if $K = 1$.

On the other hand, since reachability is transitive by construction, its symmetric, reflexive restriction $i \rightsquigarrow j \iff i \rightsquigarrow j \wedge j \rightsquigarrow i$ is a refinement of connectivity called strong connectivity. Its equivalence classes are the strongly connected components of $G$. For each disconnected component $G_k$, let $R_k$ be the number of its strongly connected components. If $R_k = 1$ then the $k$-th component is strongly
connected, otherwise just connected and composed of a number of strongly connected components itself. \( G \) is strongly connected itself if \( K = R = 1 \).

Given a digraph \( G = (V, E) \), the reduced or condensation digraph, \( \overline{G} = (\overline{V}, \overline{E}) \) is induced by the set \( \overline{V} = V/\sim \) of strongly connected components, and \( C, C' \in \overline{V} \) iff there exists one arc \((i, j) \in E\) for some \( i \in C, j \in C' \) and we say that component \( C \) has access to \( C' \), and write \( C \prec C' \). It is well known that \( \overline{G} = (\overline{V}, \overline{E}) \) is a partially ordered set called a directed acyclic graph (dag).

Given a matrix \( A \in \mathcal{M}_n(S) \), its condensation digraph is the partial order of strong connectivity classes \( \overline{G}_A = (\overline{V}_A, \overline{E}_A) \), as in Figure 2b in Example 4, of its associated digraph \( G_A = (V_A, E_A) \). This can be proven by means of an Upper Frobenius Normal Form (UFNF) \cite{12}, a structure for matrices that we intend to specialise and use as a scheme for structural induction over reducible matrices.

In the following, for a set of indices \( V_x \subseteq \mathbb{N} \) we write \( P(V_x) \) for a permutation of it, and \( E_{xy} \) is an empty matrix of conformal dimension most of the times represented on matrix patterns as elliptical dots.

**Lemma 1 (Recursive Upper Frobenius Normal Form, UFNF).** Let \( A \in \mathcal{M}_n(S) \) be a matrix over a semiring and \( \overline{G}_A = (\overline{V}_A, \overline{E}_A) \) its condensation digraph. Then,

1. (UFNF$_3$) If \( A \) has zero lines it can be transformed by a simultaneous row and column permutation of \( V_A \) into the following form:

   \[
   P^t_3 \otimes A \otimes P_3 = \begin{bmatrix}
   E_{\iota \iota} & \cdots & \cdots & \cdots \\
   \cdots & A_{\alpha \beta} & A_{\alpha \omega} & \cdots \\
   \cdots & \cdots & A_{\beta \beta} & A_{\beta \omega} & \cdots \\
   \cdots & \cdots & \cdots & E_{\omega \omega}
   \end{bmatrix}
   \] (3)

   where: either \( A_{\alpha \beta} \) or \( A_{\alpha \omega} \) or both are non-zero, and either \( A_{\alpha \omega} \) or \( A_{\beta \omega} \) or both are non-zero. Furthermore, \( P_3 \) is obtained concatenating permutations for the indices of simultaneously zero columns and rows \( V_{\iota} \), the indices of zero columns but non-zero rows \( V_{\alpha} \), the indices of zero rows but non-zero columns \( V_{\omega} \) and the rest \( V_{\beta} \) as \( P_3 = P(V_{\iota})P(V_{\alpha})P(V_{\omega})P(V_{\beta}) \).

2. (UFNF$_2$) If \( A \) has no zero lines it can be transformed by a simultaneous row and column permutation \( P_2 = P(A_1) \ldots P(A_k) \) into block diagonal UFNF

   \[
   P^t_2 \otimes A \otimes P_2 = \begin{bmatrix}
   A_1 & \cdots & \cdots \\
   \cdots & A_2 & \cdots \\
   \cdots & \cdots & \cdots \\
   \cdots & \cdots & A_K
   \end{bmatrix}
   \] (4)

   where \( \{A_k\}_{k=1}^K, K \geq 1 \) are the matrices of connected components of \( \overline{G}_A \).

3. (UFNF$_1$) If \( A \) is reducible with no zero lines and a single connected component it can be simultaneously row- and column-permuted by \( P_1 \) to

   \[
   P^t_1 \otimes A \otimes P_1 = \begin{bmatrix}
   A_{11} & A_{12} & \cdots & A_{1R} \\
   \cdots & A_{22} & \cdots & A_{2R} \\
   \cdots & \cdots & \cdots & \cdots \\
   \cdots & \cdots & \cdots & A_{RR}
   \end{bmatrix}
   \] (5)
where $A_{rr}$ are the matrices associated to each of its $R$ strongly connected components (sorted in a topological ordering), and $P_1 = P(A_{11}) \ldots P(A_{RR})$.

The particular choice of UFNF is clarified by the following Lemma, since the condensation digraph will prove important later on:

**Lemma 2 (Scheme for structural induction over reducible matrices).**

Let $A \in \mathcal{M}_n(S)$ be a matrix over an entire zerosumfree semiring and $G_A$ its condensation digraph. Then:

1. If $A$ is irreducible then $G_A \cong 1$.
2. If $A$ is in UFNF$_2$ then $G_A = \bigsqcup G_{A_k}$.
3. If $A$ is in UFNF$_3$ then $G_A = G_{A_{bb}}$.
4. $G_A = (G_A)^d$.

Note that for $A$ in UFNF$_1$, $G_A$ may be any connected ordered set.

### 3 Results

#### 3.1 Generic results for reducible matrices

The following lemma clarifies the order relation between eigenvectors in ordered semimodules,

**Lemma 3.** Let $\mathcal{X}$ be a naturally-ordered semimodule.

1. Vectors with incomparable supports are incomparable.
2. If $\mathcal{X}$ is further complete, vectors with incomparable saturated supports are incomparable.

**Proof.** Let $v$ and $w$ be two vectors in $\mathcal{X}$. Comparability of supports lies in the $\subseteq$ relation: if $\text{supp}(v) \parallel \text{supp}(w)$ then $\text{supp}(v) \not\subseteq \text{supp}(w)$ and $\text{supp}(w) \not\subseteq \text{supp}(v)$.

Therefore from $\text{supp}(v) \cap \text{supp}(w)^C \neq \emptyset$ we have $v(\text{supp}(v) \cap \text{supp}(w)^C) \neq \perp$ and $w(\text{supp}(v) \cap \text{supp}(w)^C) = \perp$, hence $v \not\leq w$. Similarly, from $\text{supp}(w) \cap \text{supp}(v)^C \neq \emptyset$ we have $w \not\leq v$, therefore $v \not\parallel w$. Claim 2 is likewise argued on the support taking the role of $\Pi$, and the saturated support taking the role of the original support.

Let $A \in \mathcal{M}_n(S)$ be a matrix and $G_A$ be its condensation digraph. Consider a class $C_r \in \nabla_A$ and call $V_u = (\bigcup_{C' \in \mathcal{C}_r} C') \setminus C_r$, $V_d = (\bigcup_{C' \in \mathcal{C}_r} C') \setminus C_r$ and $V_p = V_A \setminus (V_u \cup C_r)$ the sets of upstream, downstream and parallel vertices for $C_r$, respectively. Using permutation $P_r = P(V_u)P(C_r)P(V_p)P(V_d)$ we may suppose a blocked form of $A(C_r)$ like the one in Fig. 1 without loss of generality. Notice that any of $V_u, V_d$ or $V_p$ may be empty. However, if $V_u$ (resp. $V_d$) is not of null dimension, then $A_{ur}$ (resp. $A_{rd}$) cannot be empty.

**Proposition 3.** Let $A \in \mathcal{M}_n(K)$ be a matrix over a complete commutative selective radicable semifield with $C_r^A \neq \emptyset$. Then a scalar $\rho > \perp$ is a proper eigenvalue of $A$ if and only if there is at least one class in its condensation digraph $C_r \in G_A$ such that $\rho = \mu_{\perp}(A_{rr})$. 
A(C_r) = \begin{bmatrix}
A_{uu} & A_{ur} & A_{up} & A_{ud} \\
\cdot & A_{rr} & \cdot & A_{rd} \\
\cdot & \cdot & A_{pp} & A_{pd} \\
\cdot & \cdot & \cdot & A_{dd}
\end{bmatrix}

(a) Blocked form of \(A(C_R)\)

Fig. 1: Matrix \(A\) focused on \(C_r\), \(A(C_r) = P_r^\top \otimes A \otimes P_r\) and associated digraph. The loops at each node, consisting of (possibly empty) \(A_{uu}, A_{rr}, A_{pp}, A_{dd}\) are not shown.

**Proof.** The proof, for instance, in [8] extends even to \(\rho = \top\).

The proper spectrum is clarified by:

**Lemma 4.** Let \(A \in \mathcal{M}_n(S)\) be a reducible matrix over a complete radicable selective semifield. Then, there are no other finite eigenvectors in \(V^\rho(A)\) contributed by \(\tilde{A}^\rho\) than those selected by the critical circuits in \(C_r \in V_A\) such that \(\mu_\oplus(A_{rr}) = \rho\).

\[
\text{FEV}^\rho(A) = \bigcup_{C_r \in V_A} \{ (\tilde{A}^\rho)_{ii}^+ \mid i \in V_r^c, \mu_\oplus(A_{rr}) = \rho \}.
\]

**Proof.** If \(\rho = \mu_\oplus(A_{rr})\), from Proposition 3 we see that the finite eigenvectors mentioned really belong in \(V^\rho(A)\). If \(\rho > \mu_\oplus(A_{rr})\) then \((\tilde{A}^\rho)_{ii}^+ < e = (\tilde{A}^\rho)_{ii}^+\) hence the columns selected by \(C_r\) do not generate eigenvectors. If \(\rho < \mu_\oplus(A_{rr})\) then \((\tilde{A}_{rr})_{ii}^+ = \top\) and whether those classes with cycle mean \(\rho\) are upstream or downstream of \(C_r\) the only value that is propagated is \(\top\), hence the eigenvectors are all saturated.

**Theorem 3 (Spectra of generic matrices).** Let \(A \in \mathcal{M}_n(\overline{D})\) be a reducible matrix over an entire zerosumfree semiring. Then,

1. If \(C_A^+ = \emptyset\) then \(P(A) = P(A) = \{ \epsilon \}\).
2. If \(C_A^+ \neq \emptyset\) and further \(\overline{D}\) is a complete selective radicable semifield,
   - (a) If \(\overline{\pi}(A) \neq \emptyset\) then \(P(A) = \overline{\pi}(A) = \{ \bot \} \cup \{ \mu_\oplus(A_{rr}) \mid C_r \in V_A\}\).
   - (b) If \(\overline{\pi}(A) = \emptyset\) then \(P(A) = \overline{\pi}(A) = \{ \bot \} \) and \(P(A) = \{ \mu_\oplus(A_{rr}) \mid C_r \in V_A\}\).

**Proof.** First, call \(\overline{\pi}(A)\) the set of empty columns of \(A\). If \(G_A\) has no cycles \(C_A^+ = \emptyset\), claim 1 follows from a result in [7]. But if \(C_A^+ \neq \emptyset\) then by Proposition 3, \(P(A) \supseteq \{ \mu_\oplus(A_{rr}) \mid C_r \in V_A\}\) and no other non-null proper eigenvalues may exist by Lemma 4. \(\bot\) is only proper when \(\overline{\pi}(A) \neq \emptyset\) hence claims 2a and 2b follow.
Translating to UFNF terms:

**Corollary 1.** Let $A \in \mathcal{M}_n(\mathbb{K})$ be a matrix over a complete selective radicable semifield with $C_A^+ \neq \emptyset$. Then $P(A) = \mathbb{K}\{\perp\}$ and $P^r(A) = \{\mu_\perp(A_{rr}) \mid C_r \in \mathbf{V}_A\}$, unless $A$ is in UFNF and $\pi(A) \neq \emptyset$ whence $\perp \in P^r(A) \subseteq P(A)$ too.

**Proof.** If $A$ is irreducible or in UFNF, or UFNF, it has no empty columns or rows. This can only happen in UFNF, in which case the result follows from Theorem 3. \qed

Since this solves entirely the description of the spectrum, only the description of the eigenspaces is left pending.

### 3.2 Eigenspaces of matrices in UFNF

In this section we offer an instance of how the UFNF can be used to obtain, inductively, the spectrum of reducible matrices.

If for every parallel condensation class $C_p \subseteq \mathbf{V}_A$ in $A(C_r)$ illustrated in $C_r$ of Fig. 1 $A_{up} \neq \mathcal{E}_{up}$ or $A_{pd} \neq \mathcal{E}_{pd}$ or both, then $A$ is in UFNF with a single connected block. In this case, we can relate the order of the eigenvectors to the condensation digraph: define the support of a class $\text{supp}(C)$ as the support of any of the non-null eigenvectors it induces in $A$.

**Lemma 5.** Let $A \in \mathcal{M}_n(S)$ be a matrix in UFNF over a complete zerosumfree semiring. Then, for any class $C_r \in \mathbf{V}_A$, supp$(C_r) = \bigcup\{C_{l_r} \mid C_{l_r} \subseteq \downarrow C_r\}$.

**Proof.** Since $A_{rr}$ is irreducible, if $\rho = \mu_\perp(A_{rr})$ then for any $v_r \in V_\rho(A_{rr})$ we have that $\text{supp}(v_r) = V_r$, hence $V_r \subseteq \text{supp}(C_r)$, and $\rho$ is complete and zerosumfree $(A^\rho)^+_{rr}$ exists and is full \cite{7}. Since $(A^\rho)^+_{uu}A^\rho_{ur}$ must have a full column for any $C_{l_r} \subseteq \downarrow C_r$, meaning precisely that $C_r$ is downstream from $C_{l_r}$, the product $(A^\rho)^+_{uu}A^\rho_{ur}(A^\rho)^+_{rr}$ for the nodes in $C_{l_r}$ is non-null and $V_{l_r} \subseteq \text{supp}(C_r)$, \qed

Lemma 5 establishes a bijection between the supports of condensation classes and downsets in $\mathcal{G}_A$ which is actually an isomorphism of orders.

**Proposition 4.** Let $A \in \mathcal{M}_n(\mathbb{K})$ be a matrix over a commutative complete selective radicable semifield admitting an UFNF. Then

1. Each class $C_r \in \mathbf{V}_A$ generates a distinct saturated eigenvector, $v_r^\top$.
2. $\{v_r^\top \mid C_r \in \mathbf{V}_A\} \cong \mathcal{G}_A$.

**Proof.** Let $v \in V_\rho(A)$ where $\rho = \mu_\perp(A_{rr})$ then by Lemma 5 $\text{supp}(v) = \downarrow C_r$, hence $v_r^\top = \top v \in V_\rho(A)$ is the unique saturated eigenvector, since sat-$\text{supp}(\top v) = \text{supp}(\top v) = \text{supp}(C)$, and the bijection follows. By Lemma 3, claim 2 the order relation between classes is maintained between eigenvectors, whence the order isomorphism in claim 2. \qed
We call $\text{FEV}^{1,\top}(A) = \{v^\top \mid C_r \in \nabla A\}$ the set of saturated fundamental eigenvectors of $A$. Notice that $\nabla A^d = \nabla_A$ but $E_{A^d} = E_A^d$, so $\text{FEV}^{1,\top}(A^d) \cong \nabla_A^d$.

For every finite $\rho \in P(A)$ we define the critical nodes $V_\rho^c = \{i \in \narrow | (A^\rho)_{ii} = e\}$ and $\text{FEV}_\rho(A) = \{(A^\rho)_{ii} \mid i \in V^c\}$ the (maybe partially) finite fundamental eigenvectors of $\rho$. Next, let $\delta_{\rho}^{-1}(\rho') = e$ if $\rho' = \rho$ and $\delta_{\rho}^{-1}(\rho') = \top$ otherwise. For $\rho \in P(A)$ the set of (right) fundamental eigenvectors of $A$ in $\text{UFNF}_1$ for $\rho$ as

$$ \text{FEV}_\rho^1(A) = \cup_{\rho' \in P(A)} \{\delta_{\rho}^{-1}(\rho') \otimes \text{FEV}_{\rho'}^{1}(A)\} .$$

This definition absorbs two cases, actually,

**Lemma 6.** Let $A \in \mathcal{M}_n(\overline{\mathbb{K}})$ be a matrix over a commutative complete selective radicable semifield admitting an UFNF$_1$. Then,

1. for $\rho \in P(A) \setminus P^0(A)$, $\text{FEV}_\rho^1(A) = \text{FEV}^{1,\top}(A)$.
2. for $\rho \in P(A), \rho \neq \top$, $\text{FEV}_\rho^1(A) = \text{FEV}^{1,\top}(A) \cup \text{FEV}_\rho^1(A) \setminus (\top \otimes \text{FEV}_\rho^1(A))$.
3. for $\rho \in P(A), \rho \neq \top$, $\text{FEV}^{1,\top}(A) = \top \otimes \text{FEV}_\rho^1(A)$.

**Proof.** If $\rho \in P(A) \setminus P^0(A)$, then for all $\rho' \in \mathcal{K}$, $\delta_{\rho}^{-1}(\rho') = \top$. By Proposition 4, claim 1 follows as we range $\rho' \in P^0(A)$.

Similarly, when $\rho \in P^0(A)$, those classes whose $\rho' \neq \rho$ supply a single saturated eigenvector. However, if $\rho' = \rho$, then $\delta_{\rho}^{-1}(\rho') = e$ obtains the (partially) finite fundamental eigenvectors $\text{FEV}_{\rho'}^1(A)$, the saturated eigenvectors of which cannot be considered fundamental, since they can be obtained from $\text{FEV}_{\rho'}^1(A)$ linearly, and will not appear in $\text{FEV}_\rho^1(A)$.

Claim 3 is a corollary of the other two. $\square$

Call $V^\top(A) = (\text{FEV}^{1,\top}(A))_{\top}$ the saturated eigenspace of $A$, then

**Corollary 2.** Let $A \in \mathcal{M}_n(\overline{\mathbb{K}})$ be a matrix over a commutative complete selective radicable semifield admitting an UFNF$_1$. Then,

1. For $\rho \in P(A)$, $V^\top(A) \subseteq V_\rho(A)$.
2. For $\rho \in P(A) \setminus P^0(A)$, furthermore, $V^\top(A) = V_\rho(A)$.

**Proof.** Since we have $\text{FEV}^{1,\top}(A) \subseteq V_\rho(A)$, then $V^\top(A) \subseteq V_\rho(A)$. For $\rho \in P(A) \setminus P^0(A)$, $\text{FEV}_\rho^1(A) = \text{FEV}^{1,\top}(A)$ by Lemma 6, so claim 2 follows. $\square$

Hence, $V^\top(A)$ provides a common “scaffolding” for every eigenspace, while the peculiarities for proper eigenvalues are due to the finite eigenvectors. Also, since $V^\top(A)$ is a complete lattice, $\text{FEV}^{1,\top}(A) \subseteq V^\top(A)$ is actually a lattice embedding,

**Proposition 5.** Let $A \in \mathcal{M}_n(\overline{\mathbb{K}})$ be a matrix over a commutative complete selective radicable semifield admitting an UFNF$_1$. Then

1. For $\rho \in P(A) \setminus P^0(A)$,

$$ U^\top(A) = (\text{FEV}^{1,\top}(A^\top)^T)_3 \cong \mathcal{F}(\overline{\mathbb{G}}_A) \quad V^\top(A) = (\text{FEV}^{1,\top}(A))_3 \cong \mathcal{O}(\overline{\mathbb{G}}_A) .$$

(7)
2. for all $\rho \in P^r(A)$, $\rho < \top$

\[
U_\lambda(A) = \langle FEV^1_\lambda(A^T)^T \rangle_{K} \quad V_\rho(A) = \langle FEV^1_\rho(A) \rangle_{K} .
\]

Proof. If $v^T_r \in FEV^{1,T}(A)$ then $\lambda v^T_r = \lambda (\top v^T_r) = v^T_r$, whence $V^T(A) = (FEV^{1,T}(A))_3$. In fact, the generation process may proceed on only a subsemiring of $K$ which need not even be complete. For instance, we may use any of the isomorphic copies of 2 embedded in $K$, for instance $\{\perp, k\} \cong 2$, with $k \neq \perp$.

Since the number of saturated eigenvectors is finite, being identical to the number of condensation classes, we only have to worry about binary joins and meets. Recall that $v^T_r \lor v^T_k = v^T_r \oplus v^T_k$ and $v^T_r \land v^T_k = v^T_r \oplus v^T_k = \left((v^T_r)^{-1} \oplus (v^T_k)^{-1}\right)^{-1}$.

Then $\text{supp}(v^T_r \oplus v^T_k) = \text{supp}(v^T_r) \cup \text{supp}(v^T_k)$ and also

\[
\text{supp}(v^T_r \oplus v^T_k) = (\text{supp}^c(v^T_r) \cup \text{supp}^c(v^T_k))^c = \text{supp}(v^T_r) \cap \text{supp}(v^T_k)
\]

for $C_r, C_k \in V_A$ and Proposition 1 gives the result. For $\rho \in P^r(A)$, $FEV^1_\rho(A) \subseteq V_\rho(A)$ implies that $\langle FEV^1_\rho(A) \rangle_3 \subseteq V_\rho(A)$, and Corollary 4 ensures that no finite vectors are missing. And dually for left eigenspaces.

This actually proves that $FEV^1_\rho(A)$ is join-dense in $V_\rho(A)$.

As already mentioned, $V_\rho(A)$ is a hard-to-visualize semimodule. An eigen-space schematics is a modified order diagram where the saturated eigenspace is represented in full but the rays generated by finite eigenvalues $\{\kappa \otimes (\tilde{A}^\rho)^T i \mid i \in V^c, \rho = \mu_\otimes(A_{rr})\}$ are drawn with discontinuous lines, as in the examples below.

We are now introducing another representation inspired by (7): we define the (left) right eigenlattices of $A$ for $(\lambda \in \Lambda(A)) \rho \in P(A)$ as

\[
\mathcal{L}_\lambda(A) = \langle FEV^1_\rho(A^T)^T \rangle_3 \quad \mathcal{L}_\rho(A) = \langle FEV^1_\rho(A) \rangle_3 .
\]

Example 3 (Spectral lattices of irreducible matrices). Since irreducible matrices are in UFNF with a single class, $FEV^0_{\mu_\otimes(A)}(A) = FEV^0_{\mu_\otimes(A)}(A)$. For $\rho \in P(A) \setminus P^n(A)$ we have $FEV^{0,T}(A) = \{T^n\}$, whence $G_A \cong 1$ and $V^T(A) = \{\perp, T^n\} \cong 2$. For $\rho \in P^n(A)$, $\rho < \top$, as proven in [7], $V_{\rho}(A)$ is finitely generable from $FEV^0_{\rho}(A)$, but the form of the eigenspace and eigenlattice for $A^n(A) = \{\mu_\otimes(A)\} = P^n(A)$ depends on the critical cycles and the eigenvectors they induce.

Example 4. Consider the matrix $A \in \mathcal{M}_4(\mathcal{F}_{\text{max,}+})$ from [13, p. 25.7, example 2] in UFNF depicted in Fig. 2.(a). The condensed graph $G_A$ in Fig. 2.(b) has for vertex set $V_A = \{C_1 = \{1\}, C_2 = \{2, 3, 4\}, C_3 = \{5, 6, 7\}, C_4 = \{8\}\}$, so consider the strongly connected components $G_{A_{kk}} = (C_k, E \cap C_k \times C_k), 1 \leq k \leq 4$. Their maximal cycle means are $\mu_k = \mu_\otimes(A_{kk})$ : $\mu_1 = 0$, $\mu_2 = 2$, $\mu_3 = 1$ and $\mu_4 = -3$, respectively, corresponding to critical circuits: $C^c(G_{A_{11}}) = \{1 \otimes\}, C^c(G_{A_{22}}) = \{2 \rightarrow 3 \rightarrow 2\}, C^c(G_{A_{33}}) = \{5 \circ, 6 \rightarrow 7 \rightarrow 6\}, C^c(G_{A_{44}}) = \{8 \circ\}.$
(a) A reducible matrix in UFNF

\[
A_3 = \begin{bmatrix}
0 & 0 & 7 & \cdots \\
0 & 3 & 0 & \cdots \\
1 & \cdots & \cdots & \cdots \\
2 & \cdots & \cdots & 10 \\
\cdots & \cdots & \cdots & 0 \\
\cdots & \cdots & \cdots & -1 \\
\cdots & \cdots & \cdots & 23 \\
\cdots & \cdots & \cdots & -3
\end{bmatrix}
\]

(b) Class diagram (rectangles) overlaid on \(G_{A_3}\)

(c) Left fundamental eigenvectors

(d) Right fundamental eigenvectors

(e) \(V^T(A_3)\)

(f) Schematics of \(V_2(A_3)\)

(g) Schematics of \(V(A_3)\)

Fig. 2: Matrix \(A_3\) (a), its associated digraph and class diagram (b), its left (c) and right (d) fundamental eigenvectors annotated with their eigenvalues to the left and above, respectively; the eigenspace of improper eigenvectors \(V^T(A_3)\) in (e), a schematic of the right eigenspace of proper eigenvalue \(\rho = 2\), \(V_2(A_3)\) in (f) and the schematics of the whole right eigenspace \(V(A_3)\) in (g).
Note that node 4 does not generate an eigenvector in either spectrum, since it does not belong to a critical cycle.

Therefore $A'(A_3) = P'(A_3) = \{2, 1, 0, -3\}$ each left eigenspace is the span of the set of eigenvectors chosen from distinct critical cycles for each class of $A$: $U_{\mu_1}(A) = \langle(\tilde{A}_3^{\mu_1})_{11}^+ \rangle$, $U_{\mu_2}(A) = \langle(\tilde{A}_3^{\mu_2})_{22}^+ \rangle$, $U_{\mu_3}(A) = \langle(\tilde{A}_3^{\mu_3})_{56}^+ \rangle$, and $U_{\mu_4}(A) = \langle(\tilde{A}_3^{\mu_4})_{88}^+ \rangle$–as described by the row vectors of Fig. 2.(c)–and the right eigenspaces are $V_{\mu_1}(A) = \langle(\tilde{A}_3^{\mu_1})_{11}^- \rangle$, $V_{\mu_2}(A) = \langle(\tilde{A}_3^{\mu_2})_{22}^- \rangle$, $V_{\mu_3}(A) = \langle(\tilde{A}_3^{\mu_3})_{56}^- \rangle$, and $V_{\mu_4}(A) = \langle(\tilde{A}_3^{\mu_4})_{88}^- \rangle$–as described by the column vectors of Fig. 2.(d).

The saturated eigenspace is easily represented by means of an order diagram–Hasse diagram–as that of Fig. 2.(e). Note how it is embedded in that of any proper eigenvalue like $\rho = 2$ in Fig. 2.(f). Since the representation of continuous eigenspaces is problematic, we draw schematics of them, as in Fig. 2.(f). Fig. 2.(g) shows a schematic view of the union of the eigenspaces for proper eigenvalues $V(A_3) = \bigcup_{\rho \in P'(A)} V_{\rho}(A_3)$.

### 4 Discussion

In this paper, we have discussed the spectrum of reducible matrices with entries in completed idempotent semifields. To the extent of our knowledge, this was pioneered in [14] and both [7] and this paper can be understood as systematic explorations to try and understand what was stated in there. For this purpose, the consideration of particular UFNF forms for the matrices has been crucial: while the description in [14] is combinatorial ours is constructive.

The usual notion of spectrum as the set of eigenvectors with more than one (null) eigenvector appears in this context as too weak: when a matrix has at least one cycle then all the values in the semifield (except the bottom $\bot$) belong to the spectrum. If the matrix has at least one empty column (resp. empty row) and a cycle then all of the semifield is the spectrum. Rather than redefine the notion of spectrum we have decided to introduce the proper spectrum as the set of eigenvalues with at least one vector with finite support.

Regarding the eigenspaces, we found not only that they are complete continuous lattices for proper eigenvalues, but also that they are finite (complete) lattices for improper eigenvalues. Looking for a device to represent the information within each proper eigenspace we focus on the fundamental eigenvectors of an irreducible matrix for each eigenvalue: those with unit values in certain of their coordinates. The span of those eigenvectors by the action of the 3-bounded lattice-ordered group generates the finite eigenlattices. Interestingly, since improper eigenvectors only have non-finite coordinates, their span by the 3-blog is exactly the same finite lattice as their span by the whole semifield itself.

With these building blocks it is easy to build finite lattices for reducible matrices of any UFNF description, as exemplified above. We believe this will
be a useful technique to understand and visualize the concept lattices of formal contexts with entries in an idempotent semifield and other dioids.
